## REPORT SUMMARY

---

The goal was to test for the existence of a season extending micro-climate in high tunnels interspaces. Weather stations were deployed within both the test and control plots along with test crops of eggplant. Observations were collected on the growth and production of the crop along with collection of weather data throughout the growing season.

The field trial failed to detect any dissimilarity in empirical data between the test and control plots.

I believe a potential exists in seasons where conditions are harsher than existed during this field trial.
