

THE ECONOMICS

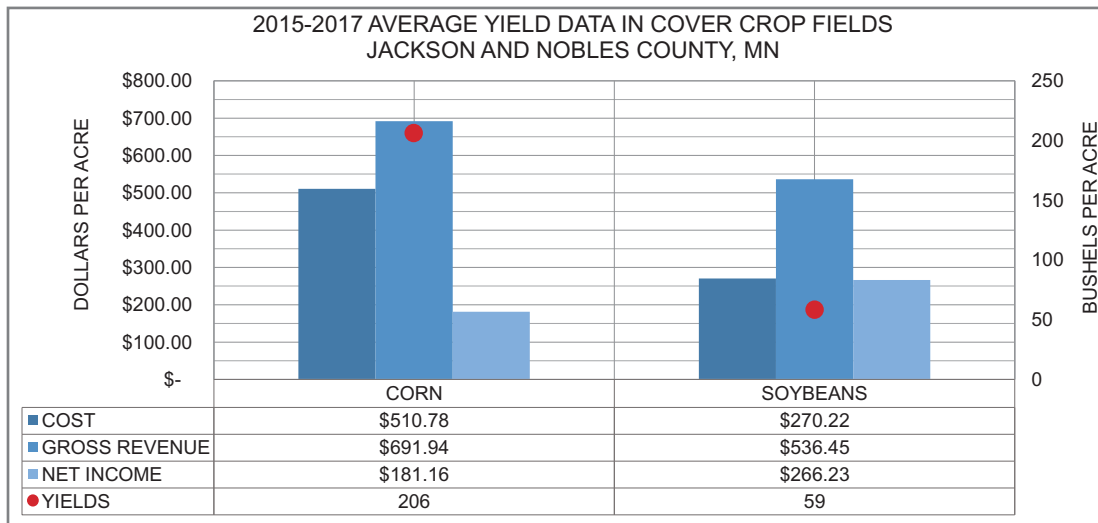

COVER CROPS ARE PROFITABLE

To help determine the economics of using cover crops, data was collected from cover crop fields in Nobles and Jackson Counties for three years. The following data was collected to determine total cost: crop seed, fertilizer, pesticides, herbicides, crop insurance, cost of using machinery (fuel, custom farming, rentals), cover crop seed, application and termination. Average yields and revenue per bushel was also collected to determine total revenue per acre. Below is a chart of the averages from corn and soybean fields from 2015-2017 in both Jackson and Nobles County.

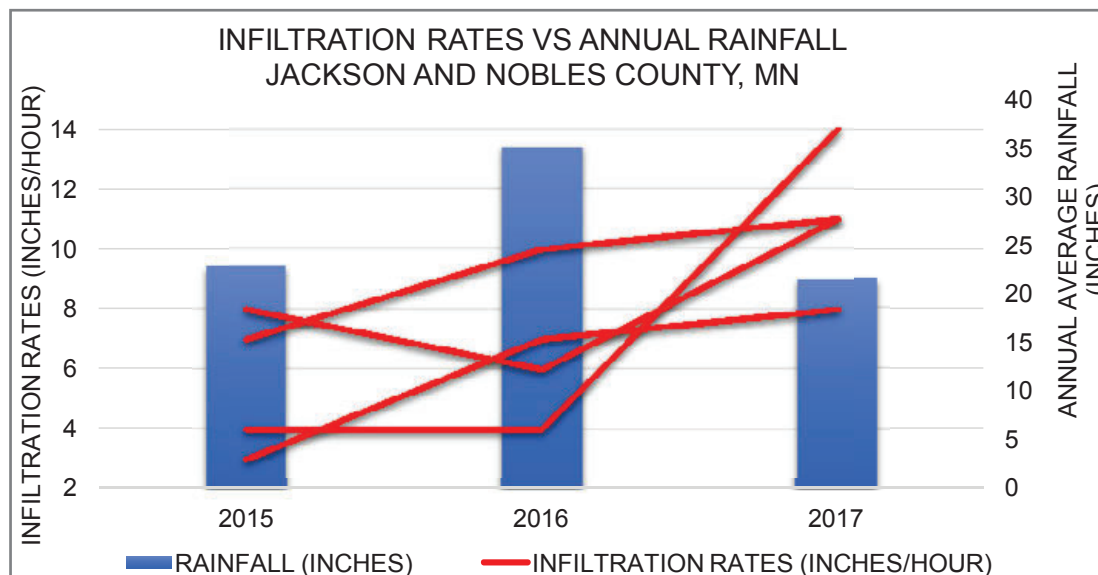

INCREASED INFILTRATION

Weather patterns are unpredictable in southwest Minnesota. Large rain events and drought conditions can happen in the same season. Farmers have been using cover crops to help manage water. Over the last three years, research plots have shown increased water infiltration on cover crop fields. During rain events, better infiltration can help water move through the soil profile and also hold soil moisture during hot summer conditions.

HIGHER YIELDS

Within the last three years, annual yield data has been collected in Jackson County and Nobles County, MN on cover crop field plots. The cover crop fields showed a higher yield a majority of the time. By using cover crops, landowners have reduced the number of tillage passes and increased yields. With these economics, farmers are still making a profit while improving soil quality, utilizing water storage, and decreasing erosion.
