J. W. Pankey, Project Coordinator, Research Professor;

J. R. Kunkel, Extension Veterinarian;

E. E. Wildman, Extension Dairy Specialist;

J. J. Goldberg, Graduate Research Fellow;

New York State Mastitis Control Program

P. M. Sears, Director, N.Y.S. Mastitis Control Program, Ithaca

## **MAJOR PARTICIPANTS**

University of Vermont, Burlington VT.: **Dr. J. Woodrow Pankey**, Research Professor, Mastitis Microbiology (Project Coordinator); **Dr. John R. Kunkel**, Extension Veterinarian; **Dr. Edward E. Wildman**, Extension Dairy Specialist; **John J. Goldberg**, Graduate Research Fellow.

Cornell University, Ithaca NY.: **Dr. Phil M. Sears**, Director, New York State Mastitis Control Program.

## **COOPERATORS**

Bovine Practitioners: **Dr. Steve Wadsworth**, St. Albans; **Dr. Joe Klopfenstein**, Vergennes; **Dr. Mark Catlin**, Barre:

Dairy Farmers (Vermont): **Edna Armstrong**, **Phil Brace**, **Brent** and **John Brigham**, **Austin Cleaves**, **Warren Davol**, **Tom Densmore**, **Conan Eaton**, **Norm and Mark Gagne**, **John and Donna Hall**, **Richard and Bonnie Hall**, **Claude and Gail Lapierre**, **Terry Magnan**, **Gordon Searls**, **Brian and Lisa Stone**, **Tim Vallee**, **Merril and Sandra Whitney**, and **Robert Wimble**.

Milk Cooperatives: **George Wilcox**, **Bob Bell**, and **Bob Friar**; Agri-Mark Milk Coop., **Jerry Booth**; Booth Bros. Creamery, **Jerry Duquet**, **Rebecca Piston**, and **John Rodgers**; Cabot Coop. Creamery, **Reginald Wedge**; Eastern Milk Producers Coop., and **Wendall Dashno**, and **Pat Cleary**; St. Albans Coop.

Vermont Quality Milk Enhancement Program (VQMEP), Vermont Dept. of Agric.: **Dan Scruton**

## **PROJECT SUMMARY**

Three grazing systems: intensively managed rotational grazing, traditional continuous grazing, and confinement housing, were compared on 17 Vermont dairy farms. The purpose was to determine if grazing systems had an effect on milk quality, animal health and reproductive efficiency.

Effect of grazing treatment on milk quality was determined by collecting bulk tank milk samples from each farm, each month for one year. The samples were analyzed by dairy cooperatives for standard plate count which is a measure of total bacterial contamination in raw milk. Results were retrieved by the University of Vermont Quality Milk Research Laboratory for analysis. Although no significant differences were determined among the grazing systems used, results did indicate trends towards improved milk quality during the summer grazing season in pastured herds compared with confined herds. During the summer grazing season (May through October), average standard plate count among herds using the rotational grazing system was 4,300 colony forming units per milliliter of

raw milk (which will be abbreviated as CFU/ml). Average count for herds using traditional grazing systems was 5,000 CFU/ml, and the average count for herds using confinement housing was 12,700 CFU/ml.

In addition to the samples evaluated by dairy cooperatives, duplicate samples were collected and sent to the University of Vermont Quality Milk Research Laboratory for analysis. These samples were analyzed for both distribution of specific bacteria types and for somatic cell count (which is a measure of the magnitude of udder infection present in the herd).

In order to determine the distribution of bacterial types, samples were incubated on a nutritive agar medium containing calf blood and the sugar esculin. Calf blood is used to determine if an organism present has toxins which cause breakdown of red blood cells and esculin is used to determine if the organism has the ability to metabolize this sugar. Sampling the milk in this manner yielded interesting trends. Non-agalactiae streptococci, which is a term describing a homogenous group of organisms found on hair, skin, and mucous membrane of cattle, as well as in soil, manure and many other locations, were more numerous in milk from farms utilizing either traditional grazing or confinement housing compared with those using rotational grazing. Determination of bulk tank milk somatic cell count indicated similar trends towards lower counts in milk from farms using rotational grazing compared with either traditional grazing or confinement.

In addition to evaluating milk quality, a survey was also conducted to determine if animal health and reproductive efficiency were impacted by the system of grazing management. Animal health and reproductive efficiency were evaluated by analyzing monthly reports by veterinarians incorporating barn records, Dairy Herd Improvement Association test reports, and records from bi-weekly or monthly herd health clinics conducted by veterinarians. As in the survey of milk quality, no significant differences were determined among the grazing systems used for animal health or reproductive efficiency. Mean occurrence of diseases, disease incidence densities, and estimates of risk were similar in all treatments for metabolic disorders, lameness and reproductive disorders. Some trends were however indicated for udder health. Udder diseases, including clinical mastitis, udder edema and teat injuries, were consistently less in herds managed on pasture compared with herds managed in confinement.

These results indicate that intensively managed rotational grazing **may** provide an environment more conducive towards improved milk quality compared with traditional continuous grazing or confinement housing methods. In addition, managing cows on pasture cows may help prevent problems related to udder health. It must be pointed out that during the period in which this study was conducted, several management changes were made on the farms surveyed. Variation of this sort is difficult to account for, and may have effected the results reported here. This study was designed as a survey. Results of this study may be used to determine sources of sampling error so that these might be controlled in future studies in this field.

## SUMMARY OF EXTENSION EFFORT

Results of LNE89-17 were presented at 6 National and statewide meetings, they were featured on a segment of The University of Vermont Extension Services television series, "Across The Fence," appeared as abstracts in two proceedings, and have been published in an international journal.

MEETINGS: Meetings that results from this trial were presented are listed in chronological order.

- 1) November 7-8, 1989. University of Vermont Extension Service - In-Service Training. Burlington, VT. 35 persons attending.
- 2) July 8-10, 1990. Northeast American Dairy Science Association/ American Society of Animal Science regional meeting. Chazy, NY. 150 persons attending.
- 3)\* November 7, 1990. LISA (Low-Input Sustainable Agriculture) Dairy Seminar. Waterbury, VT. 112 persons attending.
- 4) February 11-13, 1991. National Mastitis Council annual meeting. Reno, NV. 385 persons attending.
- 5) May 9, 1991. University of Vermont Extension Service - Pasture Walk Series. Randolph Center, VT. 20 persons attending.
- 6) May 10, 1991. University of Vermont Extension Service - Pasture Walk Series. St. Albans, VT. 15 persons attending.

\* The LISA dairy seminar, held in Waterbury, Vermont on November 7, 1990, was designed specifically to discuss with farmers, veterinarians, and dairy industry specialists how intensively managed rotational grazing can be utilized to improve profitability, sustainability, and animal health on dairy farms. As stated above, 112 people were registered to attend the meeting. The proportions of those attending were approximately 40% farmers, 15% veterinarians, 20% students from agriculture colleges, and 25% industry and research personnel. The meeting featured 14 speakers representing farmers, veterinarians, researchers, industry personnel, and extension specialists. Also featured were small discussion groups focussing both on the implications of rotational grazing as a LISA system, as well as the considerations of farmers needs when developing other LISA systems. Feedback from participants seemed promising, and ideas discussed have been implemented in subsequent proposals for LISA projects.

**PUBLICATIONS:** Results of LNE89-17 have been presented in the following publications.

## 1 ABSTRACT

2 Monthly bulk tank milk samples and veterinary records were  
3 analyzed for one year on 15 Vermont dairy farms. Data were  
4 evaluated using ANOVA to compare effects of grazing management  
5 systems on milk quality and udder health. Systems evaluated were:  
6 intensively managed rotational grazing, traditional continuous  
7 grazing, and confinement housing. Bulk tank samples were evaluated  
8 for standard plate count, bacterial type counts on tryptose blood-  
9 esculin agar, and SCC. Veterinary records were evaluated for  
10 incidence of clinical mastitis, udder edema, and teat injuries.  
11 Within and between treatment group analysis were conducted by  
12 season, herd size, and udder sanitation systems. Mean standard  
13 plate counts were lower in rotational grazed herds compared with  
14 confined herds during the grazing season. Similarly, rotational  
15 grazed herds with fewer than 60 cows had lower standard plate  
16 counts compared with confined herds of similar size. Mean bulk  
17 tank counts of non-agalactiae streptococci during the grazing  
18 season differed among treatments. Lowest counts occurred in  
19 rotational grazed herds. Among herds using predip products  
20 recognized efficacious, fewer non-agalactiae streptococci were  
21 isolated from BTM of rotational grazed herds compared with confined  
22 herds. Rotational grazed herds using postdips recognized  
23 efficacious had lower SCC's compared with those using non-  
24 recognized postdips. No udder health differences were observed  
25 among grazing treatments.

26 (Key words: grazing, bulk tank milk quality, udder health)

1 Abbreviation key: BTM = bulk tank milk, CH = confinement housing,  
2 IMI = intramammary infection, IMRG = intensively managed rotational  
3 grazing, SPC = standard plate count, TBA = tryptose blood-esculin  
4 agar, TCG = traditional continuous grazing.

## 6 Introduction

7 In recent years, more attention has been given to increasing  
8 sustainability of farming systems by reducing input costs and  
9 reliance on antibiotics and pesticides (21). This became known as  
10 Low-Input Sustainable Agriculture.

11 On the dairy farm, intensively managed rotational grazing  
12 (IMRG) has the potential of reducing feed and labor costs by  
13 increasing efficiency of pasture utilization compared to  
14 traditional continuous grazing (TCG). Cattle managed under TCG  
15 selectively grazed more palatable plant species when pasture  
16 productivity was high, leaving less palatable species (30). As a  
17 result of selective grazing, less palatable or unpalatable plant  
18 species were given a competitive growth advantage resulting in  
19 lower livestock productivity across the grazing season (30).

20 Modern dairies in the United States rely mainly on confined  
21 housing (CH) and use of stored forage and commercial concentrates  
22 to maintain milk production levels. Shift towards increased  
23 confinement has been associated with increased incidence of  
24 intramammary infection (IMI) and other udder health problems  
25 including edema and stepped on teats (1, 2). Several investigators  
26 observed that confined herds had highest incidence of clinical

1 mastitis in summer and the majority of cases were caused by  
2 environmental pathogens (4, 13, 28). In a study evaluating teat  
3 end microflora, populations of environmental pathogens on teat ends  
4 were lower on pastured cattle compared with confined cattle (5).  
5 Bulk tank milk (BTM) bacteria counts have also been shown to be  
6 lower when cows are pastured compared to confined (16). Mastitis  
7 control depends on lowering rate of new IMI and elimination of  
8 existing IMI through effective management including hygiene and  
9 therapy (4, 23, 24, 25). Use of iodophor teat dips, have resulted  
10 in increased human dietary intake of iodine from increased residues  
11 in milk (9, 10). Grazing systems that minimize teat bacterial  
12 contamination and reduce need for teat sanitizers may indirectly  
13 decrease residues in milk. Utilization of IMRG may lower teat end  
14 exposure to bacteria, decrease incidence of new IMI, decrease need  
15 for therapeutic antibiotics, and enhance BTM quality (1, 2, 3, 13,  
16 29). Common microflora can be differentiated by culturing BTM on  
17 tryptose blood-esculin agar (TBA) (20).

18         The objective of this study was to survey farms using IMRG and  
19 determine if pasture management had an effect on BTM quality and  
20 udder health. A further objective was to compare milk quality and  
21 udder health among three grazing treatments: IMRG, TCG, and CH.

1 MATERIALS AND METHODS

2 **Grazing Treatments**

3 Data were collected on 15 Vermont farms from May 1, 1989  
4 through April 30, 1990. Five farms used IMRG, five used TCG, and  
5 five used CH. The grazing treatments evaluated were initially  
6 defined by the following parameters: IMRG herds divided available  
7 pasture land into small areas (paddocks). Forage was rationed  
8 according to animal needs while protecting the plants from  
9 overgrazing (18). Period of time that cattle remained on each  
10 paddock depended on forage availability within the paddock, number  
11 of paddocks within the system, number of animals within the grazing  
12 group, number of groups, and amount of time necessary for grazed  
13 plants to recover and accumulate 15 to 20 cm of top growth.

14 Farms using TCG pastured cattle continuously on all or part of  
15 the available pasture land throughout most of the grazing season.

16 Farms using CH (zero grazing) denied cattle access to pasture  
17 and relied primarily on stored and commercial feeds to meet  
18 nutritional requirements.

19 The length of grazing season and grazing management varied  
20 among individual farms. All farms confined cattle during the  
21 winter months.

22  
23 **Criteria for Cooperator Herds**

24 Farms were nominated by three Vermont veterinary practices  
25 that cooperated in this study. Veterinarians chose farms based on  
26 breed, rolling herd average, herd size, current mastitis management

1 systems as measures of managerial ability, enrollment in DHIA, and  
2 willingness to cooperate. Each veterinary practice was required to  
3 nominate sets of three herds having similar breed, production,  
4 size, and managerial abilities. Each set had one farm for each of  
5 the three grazing treatments.

6 Management differences between farms were considered before  
7 data analysis to determine parameters consistent among all herds,  
8 and independent variables that needed to be considered for data  
9 analysis. Parameters considered included: use of lactating and dry  
10 cow therapy, milking machine system and maintenance schedule,  
11 season, herd size, and premilking and postmilking udder sanitation.

12 All farms utilized dry cow treatment on all quarters of all  
13 cows at dry off. Likewise, lactating cow antibiotics were promptly  
14 administered to quarters with clinical mastitis. Antibiotic usage  
15 was not considered as an independent management variable for  
16 statistical analysis.

17 Milking systems were evaluated on each farm (28). Most farms  
18 had some milking equipment problems, but were deemed insignificant  
19 (17). Remaining variables: season, herd size, premilking and  
20 postmilking udder sanitation, were not consistent among farms.  
21 These independent management variables were considered for  
22 statistical analysis by sorting herds by each variable prior to  
23 ANOVA.

24

## 25 **Microbiological Sampling**

26 Duplicate BTM samples were collected monthly by dairy

1 cooperative personnel. Samples were collected from each herd using  
2 standard methods (27). Samples were placed in 50ml sterile  
3 disposable Polyvial culture tubes (VWR Scientific; San Francisco,  
4 CA). One sample was evaluated for SPC by milk cooperatives using  
5 standard methods (26). The second sample was transported on ice to  
6 the Quality Milk Research Laboratory, University of Vermont, for  
7 bacteriological evaluation on TBA and for SCC (19, 20). The fat  
8 layer, where bacteria often concentrate in raw milk, was  
9 distributed throughout the sample by manually shaking the sample  
10 vial over a 30 cm arc 25 times. A .01 ml aliquot of milk was then  
11 smear plated with a sterile calibrated inoculating loop (Difco  
12 Laboratories; Detroit, MI) across the entire diameter of a TBA  
13 plate containing tryptose soy agar, 5% washed bovine blood, and .1%  
14 esculin (Micro Diagnostics; Addison Ill.) (12). All samples were  
15 streaked in duplicate. After 48h incubation at 37°C, TBA plates  
16 were evaluated to determine total count of specific bacterial types  
17 and species. Presumptive identification of microbial groups were  
18 conducted based on colony morphology, pigmentation, hemolytic  
19 reaction and esculin reaction (12, 20).

20 After streaking TBA plates, the milk sample was fixed with one  
21 drop of Preservo Liquid containing 2-Bromo-2-nitropropane-1,3-diol  
22 (D & F Control Systems Inc.; San Francisco, CA). Samples were  
23 stored at 5°C for a minimum of 24h. Within 7d of fixation, .5 ml  
24 was processed using a Fossomatic-90 Milk Cell Counter (A/S N.Foss  
25 Electric; Denmark) to measure SCC.

26

1 **Udder Health Data Collection**

2 Veterinarians that cooperated utilized a computer based herd  
3 health monitor program to aid in conducting bi-weekly or monthly  
4 herd health clinics (6, 7, 8). The monitor spreadsheet contained  
5 data provided by each farm including production, feed program, dry  
6 matter intake, body condition, animal inventory, cull program,  
7 reproduction, mastitis and disease, and calf and heifer health.  
8 Veterinarians used this information to generate monthly reports  
9 used for on farm consultations. Veterinarians then supplied copies  
10 of reports each month to the University of Vermont Quality Milk  
11 Research Laboratory through interchange of magnetic media. Reports  
12 were evaluated for incidence of clinical mastitis, udder edema, and  
13 teat injuries. Production, reproductive efficiency, and incidence  
14 of metabolic diseases were evaluated as part of a separate study  
15 (11).

16

17 **Milk Quality Data Analysis**

18 Arithmetic mean counts of milk quality parameters were  
19 transformed to  $\log_{10}$  in order to attain homogeneity of variance.  
20 Log transformed data were compared using ANOVA on Type III sums of  
21 squares (29). A maximum  $\alpha$  level of .15 was used to determine if  
22 significant differences existed which were of practical importance  
23 to producers. For each variable measured, data were ordered by  
24 grazing treatment, independent management variable, and the  
25 combination of grazing treatment and independent management  
26 variable.

1           *Season.* The study year was divided into two categories:  
2 GRAZING SEASON which included data collected from May through  
3 October, and WINTER CONFINEMENT SEASON which included data from  
4 November through April. Comparisons were conducted within and  
5 between grazing treatments to determine the effects of season.  
6 Calculations were also made based on the interaction between season  
7 and grazing treatment.

8           *Herd Size.* Farms were separated based on herd sizes. Small  
9 herds were those with less than 60 lactating cows and large herds  
10 included those with 60 or more lactating cows. Comparisons were  
11 conducted within and between grazing treatments to determine the  
12 effects of size. Calculations were also made based on the  
13 interaction between season and grazing treatment.

14           *Pre-milking Udder Hygiene.* Farms were grouped for statistical  
15 analysis based on whether the teat dip product used for predipping  
16 had been evaluated for efficacy using controlled studies. Farms  
17 utilizing a proven or unproven predip product (4, 22) were compared  
18 within and between grazing treatments to determine the effect of  
19 predip product utilized. Calculations were also made based on the  
20 interaction between season and grazing treatment.

21           *Post-milking Udder Sanitation.* Farms were grouped for  
22 statistical analysis based on whether the teat dip product used for  
23 postdipping had been evaluated for efficacy using controlled  
24 studies. Farms utilizing a proven or unproven postdip product (4,  
25 22) were compared within and between grazing treatments to  
26 determine the effect of postdip product utilized. Calculations

1 were also made based on the interaction between season and grazing  
2 treatment.

3

#### 4 **Udder Health Data Analysis**

5 Udder health was evaluated based on incidence of clinical  
6 mastitis, udder edema, and teat injuries (11). Comparisons were  
7 conducted among grazing treatments using methods of the National  
8 Animal Health Monitor System (14, 15). Data were stratified by  
9 season and herd size in order to obtain more homogeneous groups to  
10 evaluate udder health by grazing treatment (11). Analysis of  
11 variance was used to compare calculations of udder health  
12 parameters including mean occurrence, incidence density, and risk  
13 estimate among treatment groups.

14

15

### 15 **RESULTS AND DISCUSSION**

16

#### 16 **Analysis of Bulk Tank Milk Quality**

17

17 Analysis of BTM microflora indicated that all 15 cooperating  
18 herds evaluated were free of *Streptococcus agalactiae*.

19

19 *Analysis of Seasonal Effects on Milk Quality.* Standard plate  
20 count is influenced by milking machine sanitation and udder hygiene  
21 practices (16, 22). In-line sampling techniques demonstrated  
22 significant increases in bacterial populations as milk passed  
23 through a pipeline milking system (16). Evaluation of arithmetic  
24 means indicated treatment differences within the grazing season.  
25 During the grazing season, SPC was lower in IMRG compared with CH  
26 herds ( $4.05 \times 10^3$  and  $12.67 \times 10^3$  cfu/ml) ( $P < .10$ ) (Table 1). No

1 differences were observed among treatment groups for SPC during  
2 winter confinement.

3 Incidence of clinical mastitis is highest in the summer with  
4 the majority of cases caused by environmental pathogens including  
5 non-agalactiae streptococci (4, 13, 28). Bacteria counts on TBA of  
6 non-agalactiae streptococci differed among treatment groups during  
7 the grazing and winter confinement season (Table 2). During the  
8 grazing season, counts were highest in TCG herds (2242 cfu/ml) ( $P$   
9  $< .05$ ). Further comparison indicated that IMRG herds had lower  
10 counts compared with CH herds (933 and 1420 cfu/ml) ( $P < .15$ ).  
11 Observations indicate that more traditional methods of pasture  
12 management may result in a higher degree of udder contamination  
13 during the interval between milking. Managing dairy cattle in  
14 confinement may have a similar effect. The lower counts in CH  
15 compared with TCG may be the result of closer scrutiny and more  
16 intensive management among managers of confinement herds. During  
17 winter when all herds were confined, counts of non-agalactiae  
18 streptococci were higher in herds utilizing TCG compared with IMRG  
19 or CH (4,470, 1,030 and 1,800 cfu/ml) ( $P < .05$ ) (Table 2).

20 *Analysis of Herd Size Effects on Milk Quality.* Among herds  
21 with fewer than 60 lactating cows, SPC's were higher in CH herds  
22 compared with IMRG herds ( $P < .15$ ) (Table 1). Bacteria counts of  
23 non-agalactiae streptococci were lower in small and large herds  
24 using IMRG compared with those herds using TCG ( $P < .10$ ) (Table 2).  
25 When the presence of *Staphylococcus aureus* in BTM was evaluated  
26 (Table 3), herds with more than 60 cows using IMRG had lower counts

1 compared with those using TCG, (70 and 723 cfu/ml) ( $P < .15$ ).  
2 Comparison between herd sizes demonstrated higher coliform counts  
3 in IMRG herds with 60 or more lactating cows than those with less  
4 than 60 ( $P < .10$ ) (Table 4). The standard deviation of means  
5 demonstrated that management variation had a significant impact on  
6 data analysis.

7 *Analysis of Predips on Milk Quality.* Predipping with an  
8 effective product resulted in a 51% reduction in IMI from  
9 environmental pathogens (22). Untested products may not effect  
10 bacterial numbers in BTM or incidence of IMI. Herds using predips  
11 recognized as efficacious demonstrated lower TBA count of non-  
12 agalactiae streptococci in IMRG herds than CH herds (433 and 1774  
13 cfu/ml) ( $P < .05$ ) (Table 2). No TCG herds used predips that had  
14 been tested for efficacy. Analysis of data from herds using  
15 untested predips demonstrated no noticeable trends towards improved  
16 milk quality resulting from grazing management. This observation  
17 offers further testimony that the effects of improved management  
18 practices may be suppressed by insufficient hygiene prior to  
19 milking. No differences were observed between herds using tested  
20 and untested predips.

21 *Analysis of Postdips on Milk Quality.* Milk quality data from  
22 herds using untested postdips indicated trends towards lower TBA  
23 counts of *Staphylococcus aureus* in herds using IMRG compared with  
24 TCG (100 and 721 cfu/ml) ( $P < .15$ ) (Table 3). Analysis of data  
25 using postdip product as an independent management variable  
26 demonstrated a SCC reduction in IMRG herds using tested

1 postdips compared with those IMRG herds using untested postdips ( $P$   
2  $< .15$ ) (Table 5).

3 *Management Variations on Commercial Dairy Farms.* Management  
4 variations within and between herds increased sample variance and  
5 decreased power ( $1 - \beta$ ) of the model to detect significant  
6 differences at  $\alpha < .05$ . In an example, an IMRG herd initially  
7 grazed cattle at all times other than milking. In order to  
8 maximize milk production, milking frequency was changed from 2X to  
9 3X. To accommodate 3X milking, time on pasture was systematically  
10 reduced so that in barn feeding programs could be initiated. The  
11 result was a modified version of the IMRG system initially intended  
12 to be evaluated on this farm.

13 Small sample size contributed to low power in the model. When  
14 data were partitioned to account for independent management  
15 variables, number of farms evaluated in each analysis decreased,  
16 and resulted in increased standard deviation and decreased power.

17

### 18 **Analysis of Udder Health**

19 Trends were observed indicating differences in reported  
20 incidence of udder health problems among grazing treatments (Table  
21 6). Traditional continuous grazed herds reported fewer cases of  
22 udder health problems per month compared with CH herds (1.5  
23 cases/mo compared with 5.2 cases/mo.). Reported incidence of  
24 clinical mastitis was subjective among herdsman. Reported  
25 incidence may not be representative of the true incidence of  
26 clinical infections in each herd. Reports of udder edema and teat

1 injuries may have suffered from the same inconsistencies.  
2 Calculation of mean occurrence indicated that high incidence of  
3 udder health problems in CH herds resulted from high reported  
4 incidence of clinical mastitis in one herd with fewer than 60  
5 lactating cows utilizing CH (11).

6  
7

### 8 CONCLUSIONS

9 Trends appeared to demonstrate differences in milk quality  
10 among grazing treatments. Standard plate count was higher in herds  
11 using confinement housing compared with rotational grazing. Counts  
12 of bacterial types including non-agalactiae streptococci and  
13 *Staphylococcus aureus*, indicated higher contamination of BTM on  
14 farms using TCG compared with those using IMRG or CH. Coliform  
15 counts in BTM were lower in IMRG herds with less than 60 cows  
16 compared with those with 60 or more cows. Bulk tank SCC was lower  
17 in IMRG herds using tested postdips compared with those using  
18 untested postdips.

19 Effects of improved management practices may be suppressed by  
20 insufficient hygiene prior to milking. Although low sample sizes  
21 may have limited power to detect differences among treatment  
22 groups, managing cows on pasture may help reduce exposure to  
23 environmental pathogens. Adoption of rotational grazing may be a  
24 practical and profitable alternative to enhance milk quality and  
25 mastitis control. Based on trends observed, further controlled  
26 studies that minimize management variation among commercial dairy

1 herds are justified. Specific areas to be evaluated include: a)  
2 Relation of bacterial populations in bedding to environmental  
3 factors, b) Relation of bacterial populations in bedding with teat  
4 end contamination, c) Relation of environmental bacterial  
5 populations with BTM quality.

6

7

#### ACKNOWLEDGEMENTS

8 The authors acknowledge the USDA Low-Input Sustainable  
9 Agriculture project for partial funding of this project. The  
10 cooperation of all the dairymen, veterinarians, milk handlers, and  
11 the Vermont Department of Agriculture was greatly appreciated. The  
12 authors are indebted to the following people for their technical  
13 assistance: Penny Davis, Katie Deitz, Peggy Drechsler, Matt Koff,  
14 Scott Lascelles, Pat Murdough, Roger Murray, Jane O'Neil, Barbara  
15 Rikert, Amy Roche, Dan Scruton, and Mike Urbano.

<sup>a,b</sup> Means within row not sharing same superscripts differ ( $P < .15$ ).

<sup>1</sup> SS= Sums of Squares

<sup>2</sup> Column comparisons evaluate each of the four independent management variables within each grazing treatment.
